British Association for Sexual Health and HIV national guideline for the management of epididymo-orchitis (2018)

Clinical Effectiveness Group, British Association for Sexual Health and HIV

Guideline development group
Dr Mimie Chirwa (co-chair), Specialty trainee, Genitourinary medicine. Chelsea & Westminster Hospital NHS Foundation Trust, London
Dr Olubanke Davies (co-chair), Consultant, Sexual health Sutton, Chelsea & Westminster Hospital NHS Foundation Trust, London
Mrs Sheena Castelino, Pharmacist, Genitourinary medicine. Guy’s & St Thomas’ Hospitals NHS Foundation Trust, London
Dr Mbiye Mpenge, Consultant microbiologist, Weston Area Health NHS Trust, Weston-super-Mare, Somerset
Dr Farai Nyatsanza, Consultant, Genitourinary medicine, Cambridge Community Healthcare NHS Trust, Cambridgeshire
Dr Cindy Sethi, Consultant, Genitourinary medicine, Guy’s & St Thomas’ Hospitals NHS Foundation Trust, London
Dr Majid Shabbir, Consultant urologist, Guy’s & St Thomas’ Hospitals NHS Foundation Trust, London

Patient representative, recruited from a London clinic

Scope and purpose
The main objective of these guidelines is to offer recommendations on the diagnostic tests, treatment and health promotion principles in the effective management of epididymo-orchitis. It is aimed primarily at people aged 16 years or older presenting to health care professionals, working in departments offering level 3 care in STI management within the United Kingdom. However, the principles of the recommendations could be adopted at all levels.

Rigour of development
The guideline has been updated by reviewing the previous guideline (2010) and medical literature since its publication. A Medline search was performed for 2009-2017 using the keywords “epididymitis”, “orchitis” and epididymo-orchitis”. The Cochrane Database of Systematic Reviews and the Cochrane Controlled Trials Register up to 2017 were reviewed using the same keywords. Conference abstracts for British Association of Sexual Health and HIV, Federation of Infection Societies, and urology conferences were reviewed as were guidelines from Centers for Disease Control and Prevention, European Association of Urology, and International Union against Sexually Transmitted Infection guidelines. Further references from articles identified were included. Article titles and abstracts were reviewed and full texts of relevant articles reviewed. Meta-analyses of randomized controlled trials (RCTs), RCTs and systematic reviews were prioritized and recommendations were made and graded based on the best evidence available. A patient representative was recruited from a London sexual health clinic. They were involved in the development of the first and later drafts of the guideline as well as the patient information leaflet.
New in the 2018 guideline

Aetiology
Tuberculous epididymo-orchitis following BCG bladder instillation for bladder cancer.
Consideration of non-infective pathologies such as vasculitis and rare infections such as brucella where indicated in the clinical history.

Further investigations
Brucella serology should be considered in patients from a brucellosis endemic area.
CDU is not reliable enough to make a diagnosis of testicular torsion in all settings as it has a user dependent false negative rate. It is recommended that patients with suspected clinical torsion should undergo urgent exploration of the testis.

Treatment
First line empirical treatment for epididymo-orchitis most probably due to any sexually transmitted pathogen is now with ceftriaxone 1g intramuscularly and Doxycycline 100mg twice daily.
Consider 1g ceftriaxone intramuscularly + ofloxacin 200mg twice daily for epididymitis likely caused by sexually transmitted chlamydia and gonorrhoea and enteric organisms.
Consider ofloxacin 200mg twice daily or levofloxacin 500mg once daily for epididymo-orchitis most probably due to enteric pathogens.
Where Mycoplasma genitalium has been tested and identified, treatment should be guided to include an appropriate antibiotic (e.g. Moxifloxacin).

Sexual partners
Sexual partners should be tested for other STIs including HIV testing and given treatment with antibiotics to cover C. trachomatis and N. gonorrhoeae if confirmed in the index patient.

Follow up
Uropathogen confirmed epididymo-orchitis is an indication for urology referral in order to exclude structural abnormalities/urinary tract obstruction.
**Introduction**

Acute epididymo-orchitis is a clinical syndrome consisting of pain, swelling and inflammation of the epididymis +/- testes. This may result from infectious and non-infectious pathologies. The most common route of infection is local extension and is mainly due to infections spreading from the urethra (sexually transmitted pathogens) or the bladder (urinary pathogens).

**Aetiology**

**Bacterial**

- Under 35 years - most often a sexually transmitted pathogen such as *Chlamydia trachomatis* and *Neisseria gonorrhoeae* [1-12].
- Over 35 years - most often non-sexually transmitted gram negative enteric organisms causing urinary tract infections [1-12]. Particular risks include recent instrumentation (such as prostatic biopsy and vasectomy) or catheterisation [13-16].
- There is crossover between these groups and complete sexual history taking is imperative [3, 7-9, 11, 12].
- Men who engage in insertive anal intercourse are at risk of epididymitis secondary to sexually transmitted enteric organisms [1, 17, 18].
- Abnormalities of the urinary tract such as anatomical or functional abnormalities are common in the group infected with Gram negative enteric organisms. Approximately 20% of male cases with anorectal malformations (ARM) develop epididymo-orchitis [19]. In cases of suspected edidymo-orchitis with a history of ARM, a recto-urinary communication or neurogenic bladder following anoplasty should be considered [19,20].
- All patients with a confirmed urinary tract pathogen should have further investigations of the urinary tract [21,22].
- *Ureaplasma urealyticum* is found in men with epididymo-orchitis, often in association with *N. gonorrhoeae* or *C trachomatis* infection. Evidence supporting it as a common cause of epididymo-orchitis is lacking [5, 12, 23].
- *Mycoplasma genitalium* is a slow-growing microorganism, replicating intracellularly and extracellularly and is able to establish latent or chronic infections (24). An association with epididimitis is biologically plausible. It has been identified in some cases of epididymo-orchitis but evidence for its role in development of epididymo-orchitis is so far lacking [23,25].
- There has been a reported case of Panton–Valentine leukocidin (PVL) positive strain of *Staphylococcus aureus* in a healthy individual presenting with scrotal pain with folliculitis and superficial abscesses [26].

**Viral**

- Mumps is a notifiable disease which should be considered as an aetiology since the epidemic in 2005 [27]. This epidemic mainly affected non-immunised adults born between 1982 and 1986. This complication of mumps (presenting with unilateral or bilateral orchitis) can occur in up to 40% of post-pubertal males [28-30].
- Other viral pathogens such as adenovirus and enterovirus have been reported in children, presumed to be a result of post viral inflammation of the epididymis. This is a self-limiting condition [31].

**Granulomatous**

- Extrapulmonary tuberculosis represents 40-45% of TB cases in the UK [32], but tuberculous epididymo-orchitis is a rare presentation. It is likely to present in patients from high prevalence countries or with a previous history of tuberculosis and particularly in patients with immunodeficiency [33,34]. It is usually as a result of disseminated infection and commonly associated with renal TB but can be an isolated finding.
Tuberculous epididymitis has also been increasingly reported as a complication of BCG instillation for treatment of bladder carcinoma [36,37].

**Other infective causes**

- Rare infective causes include *brucella*, fungi such as candida [38], and schistosomiasis [39].
- Brucellosis should be considered in patients from endemic areas [40] such as the Mediterranean countries of Europe, north and east Africa, the Middle East, south and central Asia and Central and South America. In non-endemic countries, diagnostic suspicion should be raised in the context of travel history to an endemic area, failure to respond to first line antimicrobial therapy and/or a history of preceding fever, lethargy and night sweats [41].

**Non-infective causes**

- 12-19% of men with Behcet’s disease develop epididymo-orchitis. This is non-infective and thought to be part of the disease process. It is associated with more severe disease [42].
- Unilateral and bilateral epididymo-orchitis has also been reported as an adverse effect of amiodarone treatment and will resolve once treatment is ceased [43,44].
- Epididymo-orchitis is a rare manifestation of Henoch-Schönlein purpura (the commonest vasculitic disease in children) [45-48].
- Other rare non-infective causes include Familial Mediterranean fever [49] and polyarteritis nodosa [50,51].
Clinical features

- Patients with epididymo-orchitis typically present with acute onset unilateral scrotal pain, swelling and erythema [52].
- Patients may complain of symptoms of urethritis or urethral discharge but they may also be asymptomatic [8,9,12,53]. In addition, they may have symptoms in keeping with a urinary tract infection such as fever, dysuria, frequency and urgency.
- Testicular torsion (torsion of the spermatic cord) is the most important differential diagnosis. This is a surgical emergency that should be considered first in all patients, particularly young men, as testicular salvage is required within 6 hours and becomes decreasingly likely with time [54-56]. Testicular torsion occurs most commonly in the neonatal period and around puberty; however, it can occur at any age. The pain is typically sudden i.e. occurring within hours and severe in nature [55-57]. The pain can radiate to the groin or lower abdomen and is often associated with nausea and vomiting. Patients may also report similar pain that improved without intervention in the past (intermittent torsion). In torsion, the testis is typically more tender than the epididymis, and the torted testis is often swollen and high riding with a horizontal position. However, none of these symptoms may be present and there are no completely reliable specific clinical signs of torsion. Preliminary tests tend not to show urethritis or urinary tract infection [55,56]. If a diagnosis of epididymo-orchitis can be clearly made, then the case should be treated as such. However, if there is any doubt of the cause of the acutely painful and swollen testis, torsion should be considered until proven otherwise.

Disease specific features

- Tuberculosis: Symptoms suggestive of this include sub-acute/chronic onset of painless or painful scrotal swelling (epididymal first) which may or may not be associated with systemic symptoms of tuberculosis, scrotal sinus, and thickened scrotal skin [33,35].
- Mumps: Symptoms suggestive of this include headache and fever occurring before unilateral or bilateral parotid swelling. Patients may develop unilateral testicular swelling 7-10 days later which may present with epididymitis [58]. Mumps orchitis can occur without systemic symptoms [59].

Signs

- The presence of palpable unilateral firm swelling and tenderness of the epididymis usually starting with the tail at the lower pole of the testis and spreading towards the whole epididymis and testis should prompt treatment [60].
- There may also be:
  - Urethral discharge
  - Hydrocele
  - Erythema+/-oedema of the scrotum
  - Pyrexia
  - Patients with testicular pain post vasectomy may present with a tender unilateral fullness of the epididymis. In the absence of any other infective signs or symptoms. Confirmation of an infective element should be sought before giving antibiotics in this scenario.

Complications

- These are more often seen in patients with uropathogen-related epididymo-orchitis than sexually transmitted infection-associated epididymo-orchitis [61]. These include:
  - Reactive hydrocele
  - Abscess formation and infarction of the testicle (a rare complication) [62]
Infertility—the relationship between fertility and epididymo-orchitis is poorly understood. Mumps orchitis can lead to testicular atrophy in 30-50% of patients [63]. Of those with bilateral orchitis, 13% will have reduced infertility [63,64].
Diagnosis

Epididymo-orchitis is a clinical diagnosis that is presumptively made based on presenting history, risk of sexually transmitted infections (STIs), physical examination findings and preliminary investigations. A sexually transmitted cause should always be excluded.

Preliminary investigations:

<table>
<thead>
<tr>
<th>Test</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Gram stain of urethral smear [65]:</strong></td>
<td><strong>Microscopy:</strong> ≥ 5 polymorphonuclear leucocytes (PMNLs) per high power field (HPF) x 1000 [60,66]</td>
</tr>
<tr>
<td>Gram stain of urethral swab taken prior to micturition is highly sensitive and specific for documenting urethritis and the presence or absence of gonococcal infection [66] ([IA])</td>
<td>Presence of intracellular gram-negative diplococci [66]</td>
</tr>
<tr>
<td><strong>Urine dipstick test [67]:</strong></td>
<td><strong>Positive leukocyte esterase test [66]</strong></td>
</tr>
<tr>
<td>If dipstick testing of the first pass urine (FPU) is positive for leukocyte-esterase, it is suggestive of urethritis and lower UTI [66] ([IIB])</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>The presence of nitrite and leukocyte-esterase suggests UTI in men with urinary symptoms [, 68,69] ([IIB]). This combination demonstrated 84% specificity and a negative predictive value of 96% in one study of 8587 patients. [70]</td>
<td></td>
</tr>
<tr>
<td>A negative dipstick test should not exclude the diagnosis of UTI [68,69] ([IIIB])</td>
<td></td>
</tr>
<tr>
<td>In one study, a urine dipstick for nitrites and leukocytes showed a sensitivity and specificity for a UTI of 83% and 90% respectively in the setting of non-gonococcal urethritis [71]</td>
<td></td>
</tr>
<tr>
<td><strong>Gram stain of spun down sample from FPU [60]:</strong></td>
<td><strong>Microscopy:</strong> &gt;10 PMNLs per HFP x 1000 [60, 66].</td>
</tr>
<tr>
<td>Confirms initial urine dipstick test result ([IIIB). This may not be possible in the majority of laboratories as centrifuges may not be available.</td>
<td></td>
</tr>
</tbody>
</table>
Laboratory investigations [60, 66]:

<table>
<thead>
<tr>
<th>Test</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Mid-stream urine specimen (MSU) microscopy and culture (IA):</strong></td>
<td>Isolate of causative organism</td>
</tr>
<tr>
<td>Identifies non-gonococcal and non-chlamydial urinary pathogens</td>
<td></td>
</tr>
<tr>
<td><strong>Urethral swab for culture:</strong></td>
<td>Positive culture of <em>Neisseria gonorrhoeae</em> (<em>N. gonorrhoeae</em>)</td>
</tr>
<tr>
<td>Test takes several days to yield a result</td>
<td></td>
</tr>
<tr>
<td><strong>FPU/urethral swab for nucleic acid amplification test (NAAT) for <em>N. gonorrhoeae and Chlamydia trachomatis</em> (this has a higher sensitivity compared with culture)</strong></td>
<td>May be positive</td>
</tr>
<tr>
<td><strong>FPU for Mycoplasma genitalium (M. genitalium)</strong></td>
<td></td>
</tr>
<tr>
<td>Consider testing for <em>Mycoplasma genitalium</em> infection (IID)</td>
<td></td>
</tr>
<tr>
<td><strong>Screening for other STIs including blood borne viruses:</strong></td>
<td></td>
</tr>
<tr>
<td>Indicated in all patients with sexually transmitted epididymo-orchitis [72].</td>
<td></td>
</tr>
<tr>
<td><strong>Blood tests</strong></td>
<td>WBC, CRP and ESR may be elevated</td>
</tr>
<tr>
<td>Full blood count / white blood cell count (WBC), C- reactive protein (CRP), erythrocyte sedimentation rate (ESR)</td>
<td></td>
</tr>
</tbody>
</table>

Further investigations:

<table>
<thead>
<tr>
<th>Test</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Colour duplex ultrasonography (CDU) (IIB):</strong></td>
<td>Epididymis is enlarged and hyperaemic, with a low-resistance monophasic arterial waveform pattern [66].</td>
</tr>
<tr>
<td>CDU to assess arterial blood flow, may help differentiate between epididymo-orchitis and torsion of the spermatic cord [73]</td>
<td></td>
</tr>
<tr>
<td>CDU can help confirm the diagnosis of epididymo-orchitis and exclude the development of common complications, including infarction, reactive hydrocele and abscess formation [66].</td>
<td></td>
</tr>
</tbody>
</table>
However, CDU is *not* reliable enough to make a diagnosis of testicular torsion in all settings as it has a user dependent false negative rate [74]. In expert hands, high resolution ultrasonography can detect torsion with more accuracy with a reported sensitivity of 97.3% and specificity of 99% [75]. However, each missed diagnosis results in a non-viable testis. It is therefore recommended that patients with suspected clinical torsion should not undergo imaging in the acute setting, which may further delay diagnosis and definitive treatment, but should have an urgent scrotal exploration as this is the only situation with a reliable 100% diagnostic accuracy.

**Surgical exploration (IIIA):**
Indicated in cases where testicular torsion cannot be confidently excluded [66].

**Investigation for structural abnormalities and urinary tract obstruction by a urologist (IVC):**
Indicated in all patients with urinary tract pathogen confirmed epididymo-orchitis [76,77]. Investigation will usually include an ultrasound and CT scan of the renal tract and flexible cystoscopy.

**Investigations for suspected tuberculous epididymitis (IVC):**
- Three early morning urines for acid and alcohol-fast bacilli (AAFB)
- Intravenous urography
- Renal tract ultrasound scan
- Biopsy
- Chest x-ray: to look for co-existing respiratory disease [78]

**Mumps IgM/IgG serology (IIIB):**
Indicated when mumps orchitis is suspected [79]

- *Brucella* epididymo-orchitis has been reported in up to 20% of patients with brucellosis and therefore should be considered in a patient from a brucellosis endemic area presenting with epididymo-orchitis. Diagnosis is confirmed by *Brucella* serology (IgM and IgG) [80].
- Non-infectious causes of epididymitis are usually evident from the history e.g. history of amiodarone use or underlying vasculitis and are confirmed by negative tests for bacterial infection. Idiopathic epididymitis is a diagnosis of exclusion [66].
• There is no role for epididymal aspiration/fine needle aspiration cytology in routine clinical practice. It may be useful in recurrent infection which fails to respond to therapy and if epididymo-orchitis is found at operation and in the case of suspected tuberculous epididymitis [78,79]
Management

General advice

- Patients should be given advice on duration of symptoms, potential causes of epididymo-orchitis and possible long term complications for themselves and their partners. This can be reinforced by giving them a patient information leaflet.
- Patients should be advised to abstain from sexual intercourse until they and their partner have completed treatment and follow up in those with confirmed and suspected sexually transmitted infection [1].
- Analgesia, rest and scrotal support are recommended [81]. Scrotal support may be purchased from online retailers. Non-steroidal anti-inflammatory medications may be of benefit if not contra-indicated. (IC)
- An ultrasound of the scrotum should be considered if there is uncertainty about the clinical diagnosis or need to exclude associated complications (hydrocele, abscess, infarction).
- All patients with probable STI should be advised to attend an appropriate Sexual health (GU) clinic for STI testing. When antimicrobials are commenced in non-GU settings, a FPU for C. trachomatis and N. Gonorrhoea NAAT testing and urine dipstick/MSU should be performed and N. Gonorrhoea culture if locally available to enhance the chance of isolating the causative pathogen.

Treatment

Empirical therapy should be given to all patients with epididymo-orchitis at the time of the visit before all culture or NAAT results are available.

The antibiotic regimen chosen should be determined in light of the immediate tests (urethral smear, urinalysis). Age, history of insertive anal intercourse, recent prostate biopsy, vasectomy, urinary tract instrumentation or catheterisation and any known urinary tract abnormalities in the patient should be considered.

Antibiotics used for sexually transmitted pathogens may need to be varied according to local knowledge of antibiotic sensitivities.

Recommended Regimens

- For epididymo-orchitis most probably due to any **sexually transmitted pathogen**
  (For example: younger patient, a new sexual partner or more than one sexual partner in the past year, lack of consistent condom use and a contact of a sexually transmitted infection):
    o Ceftriaxone 1g intramuscularly single dose [1,60,82,83,84] (IC), **plus**
    o Doxycycline 100mg by mouth twice daily for 10-14 days [1,60,82,83] (IC)

- If most probably due to **chlamydia or other non-gonococcal organisms**
  (For example: where gonorrhoea has been ruled out by gram stain and no risk factors for gonorrhoea identified*):
    o Doxycycline 100mg by mouth twice daily for 10-14 days [3,12] (IC) or **plus**
    o Ofloxacin** 200mg by mouth twice daily for 14 days [7,85,86] (IB)

*Common risk factors for gonorrhoea are: previous N. gonorrhoeae infection; known contact of gonorrhoea; presence of purulent urethral discharge, men who have sex with men and multiple recent sexual partners.

**Ofloxacin treats N. gonorrhoeae, C. trachomatis and most uropathogens with good penetration into the prostate. However, it is not first line treatment for N. gonorrhoeae due to increasing bacterial resistance to quinolones [87].

- For epididymo-orchitis most probably due to an **enteric pathogen**
  (For example: older patient, not sexually active, recent instrumentation (such as prostatic bi-
opisy, vasectomy or catheterisation), men who engage in insertive anal intercourse, men with known abnormalities of the urinary tract or positive urine dipstick for leucocytes and nitrates:
  - Ofloxacin 200mg by mouth twice daily for 14 days [7,85,86] (IB) or
  - Levofloxacin 500mg by mouth once daily for 10 days [88,89,90] (IIIB)
  - If quinolones are contraindicated: Amoxycillin/clavulanate 625mg by mouth three times daily for 10 days [83] (IB)

- For acute epididymitis most likely caused by sexually-transmitted chlamydia and gonorrhoea and enteric organisms (men who practice insertive anal sex) consider
  - Ceftriaxone 1g IM in a single dose [84,88,90], plus Ofloxacin 200mg orally twice a day for 10 days [1] (IC)

- Where M. genitalium has been tested and identified, treatment should be guided to include an appropriate antibiotic (e.g. Moxifloxacin 400mg once daily for 14 days [91] (IVC)

- Corticosteroids have been used in the treatment of acute epididymo-orchitis but have not been shown to be of benefit [92,93] (IB)

- In those with severe epididymo-orchitis or features suggestive of bacteraemia in-patient management of fluid and electrolyte balance is required. Intravenous broad-spectrum therapy directed towards coliforms and Pseudomonas aeruginosa should be considered – cefuroxime 1.5g IV three times daily +/- gentamicin for 3-5 days until fever subsides and in those with severe allergy to penicillin – ciprofloxacin 500mg twice daily for 7-10 days guided by clinical response [52,94,95].

- Allergy: For epididymo-orchitis of all causes where the patient is allergic to cephalosporins and/or tetracyclines:
  - Ofloxacin 200mg by mouth twice daily for 14 days [7,85,86] (IB)

Patients should be warned of possible adverse effects of treatment. These include:

<table>

Avoid quinolones in people with a history of quinolone related tendonitis or seizures as they are at increased risk of tendon rupture and convulsions with NSAIDs (IIID)

Sexual partners
For patients with confirmed or suspected sexually transmitted epididymo-orchitis (N gonorrhoeae or C. trachomatis) all partners potentially at risk should be notified and evaluated. They should be tested for other STIs including HIV testing and given treatment with antibiotics to cover C. trachomatis and N. gonorrhoeae if confirmed in the index patient. [60,87,96]. The duration of look back is arbitrary, as the incubation period for epididymo-orchitis is unknown. Four weeks is suggested on the basis of current chlamydia guidelines [96] and two weeks or their last partner if longer ago for gonorrhoeae [87].
Follow-up
A review of cultures should be performed at 48 – 72 hours to rationalise therapy if required. If there is no improvement in the patient's condition after 3 days, the diagnosis should be reassessed and therapy re-evaluated. Further follow-up is recommended at 2 weeks to assess compliance with treatment, partner notification and improvement of symptoms. If the patient tested positive for gonorrhoea, a test of cure should be performed. If the test of cure is done by culture this should be performed at least 72 hours after completion of antimicrobial therapy. NAAT test of cure should be conducted at two weeks after completion of treatment [60]. Follow up may be done by telephone but if the patient has persisting symptoms, arrangements should be made for clinical review.

Swelling and tenderness can persist after antimicrobial therapy is completed but should be significantly improved. Swelling will have completely resolved in >80% of men by 3 months [97]. Where there is little improvement further investigations such as an ultrasound scan or surgical assessment should be considered. Uropathogen confirmed epididymo-orchitis is an indication for urology referral in order to exclude structural abnormalities/urinary tract obstruction.

Differential diagnoses to consider in these circumstances include testicular ischaemia/infarction [62,98], testicular/epididymal tumour [52], alternative infectious aetiologies such as tuberculosis, mumps or rarer infective/non-infective causes [38] and progression to an abscess [62,97].
Auditable outcomes

- The basic microbiological investigations, as recommended in the guidelines, should be performed. Target 90%
- An appropriate antibiotic regimen, as recommended in the guidelines, should be prescribed. Target 100%
- Sexual partners of men with sexually transmitted epididymo-orchitis should be tested for STIs and given treatment with antibiotics to cover *C. trachomatis* and *N. gonorrhoeae* if confirmed in the index patient. The targets achieved should be as set in the gonorrhoea and chlamydia national guidelines.
- A written action plan should be recorded for men who have not responded clinically to the initial course of antibiotics. Target 80%

Editorial independence

This guideline was commissioned and edited by the CEG of the BASHH, without external funding being sought or obtained.

Declarations of interest

All authors have declared no conflict of interest.
Clinical care pathway for management of epididymo-orchitis

Patient presents with acute unilateral scrotal pain +/- swelling

EXCLUDE TESTICULAR TORSION

Take history – age, sexual history, previous instrumentation/urological procedure or UTI?
Examination – urethral discharge?
Preliminary investigations – microscopy of urethral smear or first pass urine if available, urine dipstick
Laboratory investigations – urethral culture for N gonorrhoeae, first pass urine (FPU) for C trachomatis and N gonorrhoeae NAAT, MSU and FPU for M genitalium

Epididymo-orchitis most probably due to any sexually transmitted
• Younger patient,
• High risk sexual history (new sexual partner or multiple recent sexual partners, lack of consistent condom use)
• Contact of a STI
• No previous urological procedure or UTI
• Urethral discharge present
• Urine dipstick positive for leucocytes only

Most probably due to any STI:
• Ceftriaxone 1g IM plus doxycycline 100mg bd 10-14 days
• No sex until review

Epididymitis most likely caused by STI and enteric organisms
• STI risk factors in men who practice insertive anal sex

Most probably due to chlamydia or other non-gonococcal organisms (i.e. microscopy negative for Gram negative intra-cellular diplococci and no risk factors for gonorrhoea identified) could consider:
• Doxycycline 100mg bd 10-14 days or
• Ofloxacin 200mg bd for 14 days
• No sex until review
• Partner notification

Most probably STI and enteric organisms
• Ceftriaxone 1g IM plus Ofloxacin 200mg bd for 14 days

Follow up
Symptoms should be improving after 3 days
Further review at 2 weeks
Check laboratory results: - if gonorrhoea positive needs TOC

Symptoms and signs resolved/significantly improved
• Check compliance with treatment
• Check sexual abstinence
• Ensure PN complete

Discharge once symptoms and signs fully resolved

Symptoms and signs persist
• Check compliance with treatment
• Check sexual abstinence
• Ensure PN complete
• Review diagnosis
• Consider alternative aetiologies
• Consider testicular USS
• Consider urology referral

MSU positive
• Renal tract USS
• Referral to urology
